Chapter 8: Relational Database Design Part III. Decomposition

Lossless-join Decomposition

For the case of $R = (R_1, R_2)$, we require that for all possible relations r on schema R

$$r = \prod_{R_1}(r) \bowtie \prod_{R_2}(r)$$

- A decomposition of R into R_1 and R_2 is lossless join if at least one of the following dependencies is in F^+ :
 - $R_1 \cap R_2 \rightarrow R_1$
 - $R_1 \cap R_2 \rightarrow R_2$
- The above functional dependencies are a sufficient condition for lossless join decomposition; the dependencies are a necessary condition only if all constraints are functional dependencies.

Example

- R = (A, B, C) $F = \{A \rightarrow B, B \rightarrow C\}$
 - Can be decomposed in two different ways
- \blacksquare $R_1 = (A, B), R_2 = (B, C)$
 - Lossless-join decomposition:

$$R_1 \cap R_2 = \{B\} \text{ and } B \rightarrow BC$$

- Dependency preserving
- $R_1 = (A, B), R_2 = (A, C)$
 - Lossless-join decomposition:

$$R_1 \cap R_2 = \{A\} \text{ and } A \rightarrow AB$$

• Not dependency preserving (cannot check $B \rightarrow C$ without computing $R_1 \bowtie R_2$)

Dependency Preservation

- Let F_i be the set of dependencies F^+ that include only attributes in R_i .
 - A decomposition is **dependency preserving**, if $(F_1 \cup F_2 \cup ... \cup F_n)^+ = F^+$
 - If it is not, then checking updates for violation of functional dependencies may require computing joins, which is expensive.

Testing for Dependency Preservation

- To check if a dependency $\alpha \to \beta$ is preserved in a decomposition of R into $R_1, R_2, ..., R_n$ we apply the following test (with attribute closure done with respect to F)
 - $result = \alpha$ • while (changes to result) do • for each R_i in the decomposition • $t = (result \cap R_i)^+ \cap R_i$ • $result = result \cup t$
 - If result contains all attributes in β, then the functional dependency
 α → β is preserved.
- We apply the test on all dependencies in F to check if a decomposition is dependency preserving
- This procedure takes polynomial time, instead of the exponential time required to compute F^+ and $(F_1 \cup F_2 \cup ... \cup F_n)^+$

Example

$$R = (A, B, C)$$

$$F = \{A \rightarrow B$$

$$B \rightarrow C\}$$

$$Key = \{A\}$$

- R is not in BCNF
- Decomposition $R_1 = (A, B), R_2 = (B, C)$
 - R_1 and R_2 in BCNF
 - Lossless-join decomposition
 - Dependency preserving

Third Normal Form: Motivation

- There are some situations where
 - BCNF is not dependency preserving, and
 - efficient checking for FD violation on updates is important
- Solution: define a weaker normal form, called Third Normal Form (3NF)
 - Allows some redundancy (with resultant problems; we will see examples later)
 - But functional dependencies can be checked on individual relations without computing a join.
 - There is always a lossless-join, dependency-preserving decomposition into 3NF.

3NF Example

- Relation dept_advisor.
 - dept_advisor (s_ID, i_ID, dept_name)
 F = {s_ID, dept_name → i_ID, i_ID → dept_name}
 - Two candidate keys: s_ID, dept_name, and i_ID, s_ID
 - R is in 3NF
 - ▶ s_ID, dept_name → i_ID s_ID
 - dept_name is a superkey
 - i_ID → dept_name
 - dept_name is contained in a candidate key

Testing for 3NF

- Optimization: Need to check only FDs in F, need not check all FDs in F⁺.
- Use attribute closure to check for each dependency $\alpha \to \beta$, if α is a superkey.
- If α is not a superkey, we have to verify if each attribute in β is contained in a candidate key of R
 - this test is rather more expensive, since it involve finding candidate keys
 - testing for 3NF has been shown to be NP-hard
 - Interestingly, decomposition into third normal form (described shortly) can be done in polynomial time

3NF Decomposition Algorithm

6th edition, p. 352

```
Let F_c be a canonical cover for F;
i := 0;
for each functional dependency \alpha \rightarrow \beta in F_c do
    i := i + 1;
    R_i := \alpha \beta;
end;
if none of the schemas R_i, 1 \le i \le i contains a candidate key for R
then begin
    i := i + 1;
    R_i := any candidate key for R_i
end;
/* Optionally, remove redundant relations */
repeat
if any schema R_i is contained in another schema R_k
     then I^* delete R_i^*
       R_i = R_i;
       i=i-1:
return (R_1, R_2, ..., R_i);
```

3NF Decomposition Algorithm (Cont.)

- Above algorithm ensures:
 - each relation schema R_i is in 3NF
 - decomposition is dependency preserving and lossless-join
 - Proof of correctness is at end of this presentation (<u>click here</u>)

3NF Decomposition: An Example

Relation schema:

```
cust_banker_branch = (customer_id, employee_id, branch_name, type )
```

- The functional dependencies for this relation schema are:
 - 1. customer_id, employee_id → branch_name, type
 - 2. employee_id → branch_name
 - customer_id, branch_name → employee_id
- We first compute a canonical cover
 - branch_name is extraneous in the r.h.s. of the 1st dependency
 - No other attribute is extraneous, so we get F_C =

```
customer_id, employee_id → type
employee_id → branch_name
customer_id, branch_name → employee_id
```

3NF Decompsition Example (Cont.)

The for loop generates following 3NF schema:

```
(customer_id, employee_id, type )

(<u>employee_id</u>, branch_name)

(customer_id, branch_name, employee_id)
```

- Observe that (customer_id, employee_id, type) contains a candidate key of the original schema, so no further relation schema needs be added
- At end of for loop, detect and delete schemas, such as (<u>employee_id</u>, branch_name), which are subsets of other schemas
 - result will not depend on the order in which FDs are considered
- The resultant simplified 3NF schema is:

```
(customer_id, employee_id, type)
(customer_id, branch_name, employee_id)
```

Testing for BCNF

- To check if a non-trivial dependency $\alpha \rightarrow \beta$ causes a violation of BCNF
 - 1. compute α^+ (the attribute closure of α), and
 - 2. verify that it includes all attributes of *R*, that is, it is a superkey of *R*.
- **Simplified test**: To check if a relation schema *R* is in BCNF, it suffices to check only the dependencies in the given set *F* for violation of BCNF, rather than checking all dependencies in *F*⁺.
 - If none of the dependencies in F causes a violation of BCNF, then none of the dependencies in F⁺ will cause a violation of BCNF either.
- However, simplified test using only F is incorrect when testing a relation in a decomposition of R
 - Consider R = (A, B, C, D, E), with $F = \{A \rightarrow B, BC \rightarrow D\}$
 - ▶ Decompose R into $R_1 = (A,B)$ and $R_2 = (A,C,D,E)$
 - Neither of the dependencies in *F* contain only attributes from (*A*,*C*,*D*,*E*) so we might be mislead into thinking *R*₂ satisfies BCNF.
 - ▶ In fact, dependency $AC \rightarrow D$ in F^+ shows R_2 is not in BCNF.

BCNF Decomposition Algorithm

```
result := {R};

done := false;

compute F^+;

while (not done) do

if (there is a schema R_i in result that is not in BCNF)

then begin

let \alpha \to \beta be a nontrivial functional dependency that

holds on R_i such that \alpha \to R_i is not in F^+,

and \alpha \cap \beta = \emptyset;

result := (result -R_i) \cup (R_i - \beta) \cup (\alpha, \beta);

end

else done := true;
```

Note: each R_i is in BCNF, and decomposition is lossless-join.

Decomposing a Schema into BCNF

Suppose we have a schema R and a non-trivial dependency $\alpha \rightarrow \beta$ causes a violation of BCNF.

We decompose *R* into:

- (α U β) and
- $(R (\beta \alpha))$
- In our example,
 - α = dept_name
 - β = building, budget

and *inst_dept* is replaced by

- $(\alpha \cup \beta) = (dept_name, building, budget)$
- $(R (\beta \alpha)) = (ID, name, salary, dept_name)$

Example of BCNF Decomposition

$$R = (A, B, C)$$

$$F = \{A \rightarrow B$$

$$B \rightarrow C\}$$

$$Key = \{A\}$$

- \blacksquare R is not in BCNF ($B \rightarrow C$ but B is not a superkey)
- Decomposition
 - $R_1 = (B, C)$
 - $R_2 = (A, B)$

Example of BCNF Decomposition

- class (course_id, title, dept_name, credits, sec_id, semester, year, building, room_number, capacity, time_slot_id)
- Functional dependencies:
 - course_id→ title, dept_name, credits
 - building, room_number→capacity
 - course_id, sec_id, semester, year→building, room_number, time_slot_id
- A candidate key {course_id, sec_id, semester, year}.
- BCNF Decomposition:
 - course_id→ title, dept_name, credits holds
 - but course_id is not a superkey.
 - We replace class by:
 - course(course_id, title, dept_name, credits)
 - class-1 (course_id, sec_id, semester, year, building, room_number, capacity, time_slot_id)

BCNF Decomposition (Cont.)

- course is in BCNF
 - How do we know this?
- building, room_number→capacity holds on class-1
 - but {building, room_number} is not a superkey for class-1.
 - We replace class-1 by:
 - classroom (building, room_number, capacity)
 - section (course_id, sec_id, semester, year, building, room_number, time_slot_id)
- classroom and section are in BCNF.

BCNF and Dependency Preservation

It is not always possible to get a BCNF decomposition that is dependency preserving.

- R = (J, K, L) $F = \{JK \rightarrow L$ $L \rightarrow K\}$ Two candidate keys = JK and JL
- R is not in BCNF
- Any decomposition of R will fail to preserve

$$JK \rightarrow L$$

This implies that testing for $JK \rightarrow L$ requires a join.

BCNF and Dependency Preservation

- Constraints, including functional dependencies, are costly to check in practice unless they pertain to only one relation.
- If it is sufficient to test only those dependencies on each individual relation of a decomposition in order to ensure that all functional dependencies hold, then that decomposition is dependency preserving.
- Because it is not always possible to achieve both BCNF and dependency preservation, we consider a weaker normal form, known as third normal form.

Comparison of BCNF and 3NF

- It is always possible to decompose a relation into a set of relations that are in 3NF such that:
 - the decomposition is lossless
 - the dependencies are preserved
- It is always possible to decompose a relation into a set of relations that are in BCNF such that:
 - the decomposition is lossless
 - it may not be possible to preserve dependencies.

Design Goals

- Goal for a relational database design is:
 - BCNF.
 - Lossless join.
 - Dependency preservation.
- If we cannot achieve this, we accept one of
 - Lack of dependency preservation
 - Redundancy due to use of 3NF
- Interestingly, SQL does not provide a direct way of specifying functional dependencies other than superkeys.
 - Can specify FDs using assertions, but they are expensive to test, (and currently not supported by any of the widely used databases!)
- Even if we had a dependency preserving decomposition, using SQL we would not be able to efficiently test a functional dependency whose left hand side is not a key.
